#### Markov matrix with discrete state space

Define a set of states for Y/L:  $s = \{s_1, s_2, ..., s_K\}$ .

The **probability** of region *i* to transit from state *k* to state *q* with lag  $\tau$  is defined as:

$$p_{qk} = \Pr(Y/L_{i,t+\tau} \in s_q | Y/L_{i,t} \in s_k).$$
(1)

If the dynamics of distribution follows a **Markov process**, then the dynamics of the masses of probability related to different states can be represented by:

$$\pi_{t+\tau} = \pi_t P, \tag{2}$$

where  $\pi_t = (\pi_{1,t}, ..., \pi_{K,t})$  (row vector) and  $\pi_{k,t}$  is the mass of probability of distribution in state k at period t and P, which collect all  $p_{qk}$ , is called the **Markov transition matrix** (dimensions  $K \times K$ ). Under some regularity conditions there exists an **ergodic (equilibrium)** 

**distribution**  $\pi_{\infty}$  such that:

$$\pi_{\infty} = \pi_{\infty} P. \tag{3}$$

#### Markov matrix with continuous state space

The definition of the state space may crucially affect the result. Possible solution: **the use of continuous state space**.

Markov matrix with continuous state space becomes a **conditioned distribution**, also denoted **stochastic kernel**:

$$g_{\tau}\left(Y/L_{i,t+\tau}|Y/L_{i,t}\right) \equiv \frac{f\left(Y/L_{i,t+\tau},Y/L_{i,t}\right)}{r\left(Y/L_{i,t}\right)}$$

Accordingly the ergodic distribution solves:

$$f_{\infty}(x) = \int_{0}^{\infty} g_{\tau}(x|z) f_{\infty}(z) dz, \qquad (4)$$

where x and z are two levels of Y/L,  $g_{\tau}(x|z)$  is the density of x, given z,  $\tau$  periods ahead, under the constraint

$$\int_{0}^{\infty} f_{\infty}(x) \, dx = 1. \tag{5}$$

#### Ergodic distribution

# Ergodic distribution with normalized variable

Since in our estimates all variables are normalized with respect to their average, the ergodic distribution must respect the additional constraint:

$$\int_{0}^{\infty} f_{\infty}(x) \, x dx = 1. \tag{6}$$

Then the true ergodic distribution is:

$$f_{\infty}\left(x\right) = \tilde{\mu}_{x}\tilde{f}_{\infty}\left(x\right),\tag{7}$$

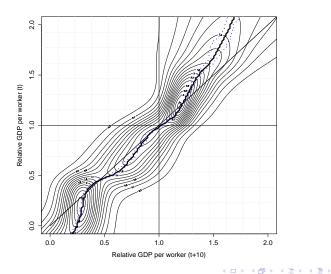

where:

$$\tilde{\mu}_{x} = \int_{0}^{\infty} \tilde{f}_{\infty}(x) \, x dx \tag{8}$$

and  $\tilde{f}_{\infty}$  satisfies Eqq. (4) and (5).

#### Stochastic kernel

# Stochastic kernel

Brunetti-Fiaschi-Parenti

:▶ ◀ 볼 ▶ 볼 ∽ ९. 07/10/2016 13 / 14

# Median of the stochastic kernel

The bold line represents the **median** of the estimated conditioned distribution  $g_{\tau}(Y/L_{i,t+\tau}|Y/L_{i,t})$ , denoted by med  $(Y/L_{i,t})$ . The median is crucial to understand the dynamics of the **mass of distribution**; in particular:

- if med (Y/L<sub>i,t</sub>) > Y/L<sub>i,t</sub> then we expect that locally the mass is shifting ahead around Y/L<sub>i,t</sub>
- if med  $(Y/L_{i,t}) < Y/L_{i,t}$  then we expect that **locally** the mass is shifting behind around  $Y/L_{i,t}$
- if med  $(Y/L_{i,t}) = Y/L_{i,t}$  then we expect that **locally** the mass is stable around  $Y/L_{i,t}$ , i.e.  $Y/L_{i,t}$  is a possible **equilibrium**.

Another perspective to see the estimated stochastic kernel is to think about it how a stochastic difference equation:

$$Y/L_{i,t+\tau} = \phi\left(Y/L_{i,t}\right) + \varepsilon_{i,t+\tau} \tag{9}$$

 $\Rightarrow$  if around an equilibrium med  $(Y/L_{i,t})$  crosses from below, this equilibrium is **stable**, if it crosses from above, this equilibrium is **unstable**.

Brunetti-Fiaschi-Parenti
