Some Remarks on Generalize Additive Models (GAMs)

A generalize additive model is a generalized linear model with a linear predictor involving a smooth function of the covariate:

$$y_i = s(x_i) + \epsilon_i \tag{2}$$

where y_i is the response variable, x_i the covariate, $s(\cdot)$ a smooth function and ϵ_i are i.i.d. $N(0, \sigma^2)$.

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

A generalize additive model is a generalized linear model with a linear predictor involving a smooth function of the covariate:

$$y_i = s(x_i) + \epsilon_i \tag{2}$$

where y_i is the response variable, x_i the covariate, $s(\cdot)$ a smooth function and ϵ_i are i.i.d. $N(0, \sigma^2)$.

To estimate $s(\cdot)$, let represent it is such a way that Eq. (2) becomes a linear model by choosing a *basis* function:

$$s(x) = \sum_{j=1}^{q} b_j(x)\beta_j$$
(3)

for some values of the unknown parameters.

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Polynomial bases have some problems in estimating on the whole domain of x. Alternatively, the **spline** bases perform well.

Polynomial bases have some problems in estimating on the whole domain of x. Alternatively, the **spline** bases perform well.

A cubic spline is a curve, made up of sections of cubic polynomial, joined together so that they are continuous in value as well as first and second derivatives. The points at which the sections join are known as the **knots** of the spline

Knots must be chosen!

Brunetti-Fiaschi-Parenti

Quantitative Economics

Given knot location, how do we choose the **degree of smoothing** (i.e. the basis dimension)?

One way, is to keep the basis dimension fixed, at a size a little larger than it is believed could reasonably be necessary, but to control the models smoothness by adding a wiggliness penalty to the least squares fitting objective.

Given knot location, how do we choose the **degree of smoothing** (i.e. the basis dimension)?

One way, is to keep the basis dimension fixed, at a size a little larger than it is believed could reasonably be necessary, but to control the models smoothness by adding a wiggliness penalty to the least squares fitting objective.

For example, rather than fitting the model by minimizing:

$$\|\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\|^2 \tag{5}$$

it could be fit by minimizing,

$$\|\mathbf{y} - \mathbf{X}\beta\|^2 + \lambda \int [s''(\mathbf{x})]d\mathbf{x}$$
(6)

where the integrated square of second derivative penalizes models that are too wiggly.

it could be fit by minimizing,

$$\|\mathbf{y} - \mathbf{X}\beta\|^2 + \lambda \int [s''(\mathbf{x})]d\mathbf{x}$$
(6)

where the integrated square of second derivative penalizes models that are too wiggly. The trade off between model fit and model smoothness is controlled by the *smoothing* parameter, λ . $\lambda \to \infty$ leads to a straight line estimate for *s*, while $\lambda = 0$ results in an un-penalized regression spline estimate.

Brunetti-Fiaschi-Parenti

26/10/2017 5 / 15

イロト 不得 トイヨト イヨト 二日

Given that s is linear in parameters β the penalty can be written as a quadratic form:

$$\lambda \int [s''(x)]dx = \beta' \mathbf{S}\beta \tag{7}$$

where \mathbf{S} is a matrix of known coefficients.

Therefore the penalized regression spline problem is to minimize:

$$\|\mathbf{y} - \mathbf{X}\beta\|^2 + \lambda\beta'\mathbf{S}\beta \tag{8}$$

$$\rightarrow \hat{\beta} = (\mathbf{X}'\mathbf{X} + \lambda \mathbf{S}')^{-1}\mathbf{X}'\mathbf{y}$$
(9)

 λ must be chosen!! Too high λ leads to over-smoothing while too low λ to under-smoothing \rightarrow generalized cross-validation.

26/10/2017 6 / 15

Both with the over-smoothing (too high λ) and the under-smoothing (too low λ) the spline estimate \hat{f} will not be close to the true function f.

Ideally, it would be good to choose λ so that \hat{f} is as close as possible to f.

A suitable criterion might be to choose λ to minimize:

$$M = \frac{1}{n} \sum_{i=1}^{n} (\hat{f}_i - f_i)^2$$
(10)

Problem: *f* is no observable!

It is possible to derive an estimate of $E(M) + \sigma^2$ which is the expected squared error in predicting a new variable.

Let \hat{f}^{-i} be the model fitted to all data except y_i and define the *ordinary cross validation* score:

$$V_0 = \frac{1}{n} \sum_{i=1}^{n} \left(\hat{f}^{-i} - y_i \right)^2 \tag{11}$$

This score results from leaving one out each datum in turn, fitting the model to the remaining data and calculating the squared difference between the missing datum and its predicted value: these suared differences are the averaged over all data

It is computationally inefficient to calculate V_0 by leaving one out one datum at a time, and fitting the model to each of the *n* resulting datasets.

But it can be shown that:

$$V_0 = \frac{1}{n} \sum_{i=1}^{n} (y_i - \hat{f}_i)^2 / (1 - A_{ii})^2$$
(12)

where \hat{f} is the estimate from fitting all the data and A is the corresponding influence matrix.

In practice, the weights $(1 - A_{ii})$ are often replaced by the mean weights tr(I - A)/n, in order to arrive at the generalized cross validation.

When we have and additive model with more than one covariate as for example:

$$y_i = s_1(x_i) + s_2(z_i) + \epsilon_i \tag{13}$$

the parameters β are obtained by minimization of the penalized least squares objective:

$$\| \mathbf{y} - \mathbf{X}\beta \|^2 + \lambda_1 \beta' \mathbf{S}_1 \beta + \lambda_2 \beta' \mathbf{S}_2 \beta$$
(14)
